1-(2-Methyl-5-nitrophenyl)guanidinium picrate

Jerry P. Jasinski,^a Ray J. Butcher,^{b*} M. T. Swamy,^c H. S. Yathirajan^c and A. R. Ramesha^d^aDepartment of Chemistry, Keene State College, 229 Main Street, Keene, NH 03435-2001, USA, ^bDepartment of Chemistry, Howard University, 525 College Street NW, Washington, DC 20059, USA, ^cDepartment of Studies in Chemistry, University of Mysore, Manasagangotri, Mysore 570 006, India, and ^dRL Fine Chem, Bangalore 560 064, IndiaCorrespondence e-mail: rbutcher99@yahoo.com

Received 13 July 2009; accepted 17 September 2009

Key indicators: single-crystal X-ray study; $T = 110$ K; mean $\sigma(\text{C}-\text{C}) = 0.002$ Å; R factor = 0.041; wR factor = 0.118; data-to-parameter ratio = 12.3.

In the crystal structure of the title salt, $\text{C}_8\text{H}_{11}\text{N}_4\text{O}_2^{+}\cdot\text{C}_6\text{H}_2\text{N}_3\text{O}_7^{-}$, the picrate anion participates in extensive hydrogen bonding with the guanidinium ion group of the cation, linking the molecules through $\text{N}^+\cdots\text{H}\cdots\text{O}^-$ hydrogen bonds and intermolecular $\text{N}-\text{H}\cdots\text{O}$ and $\text{C}-\text{H}\cdots\text{O}$ interactions. These hydrogen-bonding configurations involve two three-centre/bifurcated bonds [$\text{N}-\text{H}\cdots(\text{O},\text{O})$] that are observed between two N atoms from the guanidinium ion group of the cation and the *o*-NO₂ and phenolate O atoms of the picrate anion. In addition, π - π interactions also contribute to the crystal packing, with a centroid-to-centroid distance of 3.693 (6) Å and a slippage angle of 1.614°. A significant number of conformational differences are observed between the salt in the crystal structure and the models obtained by density functional theory (DFT) calculations of the geometry-optimized structure.

1-(2-Methyl-5-nitrophenyl)guanidinium picrate

Jerry P. Jasinski, Ray J. Butcher, M. T. Swamy, H. S. Yathirajan and A. R. Ramesha

S1. Comment

Guanidines, important compounds that have many biological, chemical and medicinal applications (Berlinck, 2002; Heys *et al.*, 2000), have received increasing interest as medicinal agents with antitumour, antihypertensive, antiglaucoma and cardiotonic activities (Laeckmann *et al.*, 2002; Kelley *et al.*, 2001; Moroni *et al.*, 2001). Due to their strong basic character, they can be considered as super-bases that readily undergo protonation to generate resonance-stabilized guanidinium cations (Ishikawa & Isobe, 2002). Guanidine is used in variety of supramolecular recognition processes across the spectrum of organic, biological and medicinal chemistry (Orner & Hamilton, 2001) with special interest motivated by their potential applications in non-linear optics (Zyss *et al.*, 1993).

The crystal structures of a few related guanidine derivatives *viz.* guanidinium 2-amino-4-nitrobenzoate monohydrate at 130 K (Smith *et al.*, 2007), (2,4,6-trinitrophenyl)guanidine (Smith *et al.*, 2007*a*), 4-methoxy-phenylguanidinium chloride (Ren *et al.*, 2007), (*E*)-1-[(2-methoxyphenyl)methyleneamino]guanidinium chloride (Sonar *et al.*, 2007), have been reported. 1-(2-methyl-5-nitrophenyl)guanidine is one of the starting compounds for the synthesis of the anticancer drug, imatinib. In connection with the importance of guanidine derivatives, the present paper reports the crystal structure of the title compound, (I), C₁₄H₁₃N₇O₉.

The title compound, (I), crystallizes as a salt with one independent cation–anion pair [C₈H₁₁O₂N₄⁺.C₆H₂N₃O₇[−]] in the asymmetric unit (Fig. 1). Bond lengths and angles can be regarded as normal (Cambridge Structural Database, Version 5.30, February, 2009; Allen, 2002, *Mogul*, Version 1.1.3; Bruno *et al.*, 2004). In the cation, the angle between the dihedral planes of the guanidinium ion [(CH₃N₃)⁺] and the bonded 2-methyl-5-nitrophenyl group is 83.0 (7)°. All three nitrogen atoms (N2A, N3A & N4A) exhibit *sp*² hybridization with a sum of angles around each atom of 360.0 (0)° resulting in a planar guanidinium ion group. The dihedral angle between the mean planes of the 5-nitro group and the benzyl ring is 5.0 (3)°. In the picrate anion, the mean plane of two *o*-NO₂ and single *p*-NO₂ groups are twisted by 14.6 (4)°, 16.6 (3)° and 5.6 (8)°, respectively, from the mean plane of the benzyl ring. The difference in the twist angles of the mean planes of the two *o*-NO₂ groups can be attributed to an intermolecular hydrogen bonded interaction between the guanidinium ion of the cation with both of these groups (O21B—N2B—O22B & O61B—N6B—O62B) of the picrate anion, in which the O21B and O62B atoms form intermolecular "side" hydrogen bonds (N4A—H4AA⋯O21B & N3A—H3AB⋯O62B) with N4A and N3A from the guanidinium ion (Fig. 2, Table 1). N4A and N3A also both form intermolecular hydrogen bonds with the phenolate oxygen anion O1B (N4A—H4AA⋯O1B & N3A—H3AB⋯O1B), each creating a bifurcated (three-centre), N—H⋯(O,O) hydrogen bond. As a result, O1B and O21B act as the double acceptors. N4A and N3A form additional intermolecular hydrogen bonds with nearby O21B (N4A—H4AB⋯O21B) and O1A (N3A—H3AC⋯O1A) atoms, respectively. The dihedral angle between the mean planes of the benzyl ring and guanidinium ion group in the cation and the benzyl ring of the picrate anion are 80.8 (7)° and 7.4 (7)°, respectively. Additional weak N2A—H2AA⋯O22B and C3A—H3AA⋯O41B hydrogen bonds and π – π stacking interactions occur (*Cg*1⋯*Cg*1 = 3.693 (6) Å; $-x, 1-y, -z$; slippage = 1.614°; *Cg*1 = C1A–C6A centroid) contributing to the stability of crystal packing.

A density functional theory (DFT) geometry optimization molecular orbital calculation (Schmidt & Polik, 2007) was performed on the $\text{C}_8\text{H}_{11}\text{O}_2\text{N}_4^+.\text{C}_6\text{H}_2\text{N}_3\text{O}_7^-$ cation–anion pair of the title molecule, (I), with the *GAUSSIAN03* program package (Frisch *et al.* 2004) employing the B3LYP (Becke three parameter Lee–Yang–Parr) exchange correlation functional, which combines the hybrid exchange functional of Becke (Becke, 1988, 1993) with the gradient-correlation functional of Lee, Yang and Parr (Lee *et al.* 1988) and the 3-21G basis set (Hehre *et al.* 1986). Starting geometries were taken from X-ray refinement data. The dihedral angle between the dihedral planes of the guanidinium ion $[(\text{CH}_3\text{N}_3)^+]$ and the bonded 2-methyl-5-nitrophenyl group in the cation decreases by $7.1\ (2)^\circ$ to $70.9\ (1)^\circ$ while the mean plane of the 5-nitro group decreases by $5.0\ (3)^\circ$ to become planar with the benzyl ring. In the picrate anion, the twist of the mean planes of two *o*-NO₂ and single *p*-NO₂ groups decreases by $12.3\ (1)^\circ$, $10.4\ (9)^\circ$ and $5.6\ (8)^\circ$ to $4.3\ (2)^\circ$, $4.1\ (5)^\circ$ and $0.0\ (0)^\circ$, respectively, from the mean plane of the 6-membered benzyl ring. The dihedral angle between the mean planes of the benzyl ring and guanidinium ion group in the cation and the benzyl ring of the picrate anion change by $-17.8\ (5)^\circ$ and $+2.1\ (9)^\circ$ to $63.0\ (2)^\circ$ and $9.6\ (6)^\circ$, respectively. Examination of the partial charges from the DFT geometry optimization indicate that H4AA (0.44384) is slightly more positive than H3A (0.402348) producing a slightly delocalized proton charge over the guanidinium group and favoring the N4A atom. This coincides with a shorter N4A—H4AA \cdots O1B (= 1.984 Å) hydrogen bond than N3A—H3A \cdots O1B (= 2.033 Å) due to the multiple acceptor function of O1B. In conclusion, the significant number of conformational changes that are observed between the crystalline environment of this cation–anion (1-(2-methyl-5-nitrophenyl)guanidinium picrate) salt and that of a density functional theory calculation of the geometry optimized structure support the effects of strong intermolecular hydrogen bonding interactions and weak π – π ring intermolecular interactions between the guanidinium ion and bonded 2-methyl-5-nitrophenyl group of the cation and the *o*-NO₂, *p*-NO₂ and phenolate oxygen groups of the picrate anion as providing the major influence on packing effects in the crystal of the title compound, 1-(2-methyl-5-nitrophenyl)guanidinium picrate, (I).

S2. Experimental

The title compound was synthesized by adding a solution of picric acid (0.92 g, 2 mmol) in 10 ml of methanol to a solution of 1-(2-methyl-5-nitrophenyl)guanidine (0.45 g, 2 mmol) in 10 ml of methanol (Scheme 2). A yellow colour developed and the solution was allowed to evaporate slowly at room temperature. The yellow colour compound formed was filtered off, washed several times with diethyl ether, and then dried over CaCl₂ (yield: 64.2%). Crystals for X-ray studies were grown by slow evaporation of dimethyl formamide solution. The melting range was found to be 382–385 K. Analysis found (calculated) for $\text{C}_{14}\text{H}_{13}\text{N}_7\text{O}_9$ (%): C: 39.95 (39.72), H: 2.99 (3.1), N: 23.36 (23.16).

S3. Refinement

All of the H atoms were placed in their calculated positions and then refined using the riding model with N—H = 0.88, C—H = 0.95 Å, and with $U_{\text{iso}}(\text{H}) = 1.17\text{--}1.51 U_{\text{eq}}(\text{C}, \text{N})$.

**Figure 1**

The asymmetric unit of (I), showing the bifurcated (three-centre) N—H \cdots (O,O) donor hydrogen bond configuration and the atom labeling scheme. Hydrogen bonds are shown as dashed lines. Displacement ellipsoids are shown at the 50% probability level.

**Figure 2**

Packing diagram of the title compound, (I), viewed down the *b* axis. Dashed lines indicate intermolecular bifurcated (three-centre) N—H \cdots (O,O), N—H \cdots O, and C—H \cdots O donor hydrogen bond interactions which produces a 2-D network arranged along the (101) plane.

Special details

Experimental. CrysAlisPro, Oxford Diffraction Ltd., Version 1.171.33.34d (release 27-02-2009 CrysAlis171 .NET) (compiled Feb 27 2009, 15:38:38) Empirical absorption correction using spherical harmonics, implemented in SCALE3 ABSPACK scaling algorithm.

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
